## CONVERSION FACTORS, VERTICAL DATUM, ABBREVIATED WATER-QUALITY UNITS, AND ACRONYMS

Multiply	By	To obtain
acre	4,047	square meter
cubic foot per second (ft <sup>3</sup> /s)	0.028317	cubic meter per second
foot (ft)	0.3048	meter (m)
gallon per minute (gal/min)	0.06309	liter per second
inch (in.)	25.4	millimeter (mm)
mile (mi)	1.609	kilometer
square mile (mi <sup>2</sup> )	2.59	square kilometer

Degree Celsius (°C) may be converted to degree Fahrenheit (°F) by using the following equation:

$$^{\circ}\text{F} = 9/5\ (^{\circ}\text{C}) + 32$$

**Sea level:** In this report "sea level" refers to the National Geodetic Vertical Datum of 1929 (NGVD of 1929)--a geodetic datum derived from a general adjustment of the first-order level nets of both the United States and Canada, formerly called Sea Level Datum of 1929.

Chemical concentration in water is reported in milligrams per liter (mg/L) or micrograms per liter (µg/L). Milligrams per liter is a unit expressing the solute mass (milligram) per unit volume (liter) of water and is about the same as parts per million unless concentrations are more than 7,000 milligrams per liter (Hem, 1985, p. 55). One thousand micrograms per liter is equivalent to 1 milligram per liter. Tritium concentration is expressed in tritium units (TU). A tritium unit is equal to 3.2 picocuries per liter (pCi/L), which is equal to 2.2 radioactive disintegrations per minute in a unit volume (liter) of water.

**Abbreviated water-quality units used in this report:**

$\mu\text{g/L}$	micrograms per liter
$\mu\text{S/cm}$	microsiemens per centimeter at 25 degrees Celsius
$\text{mg/L}$	milligrams per liter
permil	parts per thousand
TU	tritium unit

**Acronyms used in this report:**

WATSTORE	Water-Data Storage and Retrieval System

# **HYDROLOGIC AND WATER-QUALITY DATA RELATED TO THE OCCURRENCE OF ARSENIC FOR AREAS ALONG THE MADISON AND UPPER MISSOURI RIVERS, SOUTHWESTERN AND WEST-CENTRAL MONTANA**

*By L.K. Tuck, DeAnn M. Dutton, and David A. Nimick*

## **Abstract**

Geothermal waters in Yellowstone National Park contribute large quantities of arsenic to the headwaters of the Madison River, which, in part, forms the upper Missouri River. Water in some Quaternary and Tertiary valley-fill deposits along the Madison and upper Missouri Rivers also is locally enriched in arsenic. Arsenic in surface and ground water in these valleys is an important public-health concern because arsenic concentrations frequently exceed the State of Montana water-quality human health standard of 18 micrograms per liter as well as the U.S. Environmental Protection Agency Maximum Contaminant Level of 50 micrograms per liter.

This report presents hydrologic and water-quality data for the Madison and upper Missouri Rivers and selected tributaries, irrigation supply canals or ditches, drains, springs and seeps, for Lake Helena, and for ground water in adjacent areas. Hydrologic and water-quality data were collected and compiled to provide information to more fully understand the extent, magnitude, and source of arsenic in surface and ground water along the Madison and upper Missouri Rivers; to assess, to the extent possible, the mechanisms that control arsenic concentrations; and to assess the effect of irrigation on arsenic concentrations. Hydrologic and arsenic-concentration data were collected by the U.S. Geological Survey and other agencies for 104 surface-water sites and 273 ground-water sites during this and previous studies. The quality of analytical results for arsenic concentrations was evaluated by quality-control samples that were submitted from the field and analyzed in the laboratory with routine samples. Quality-control samples consisted of replicates, standard refer-

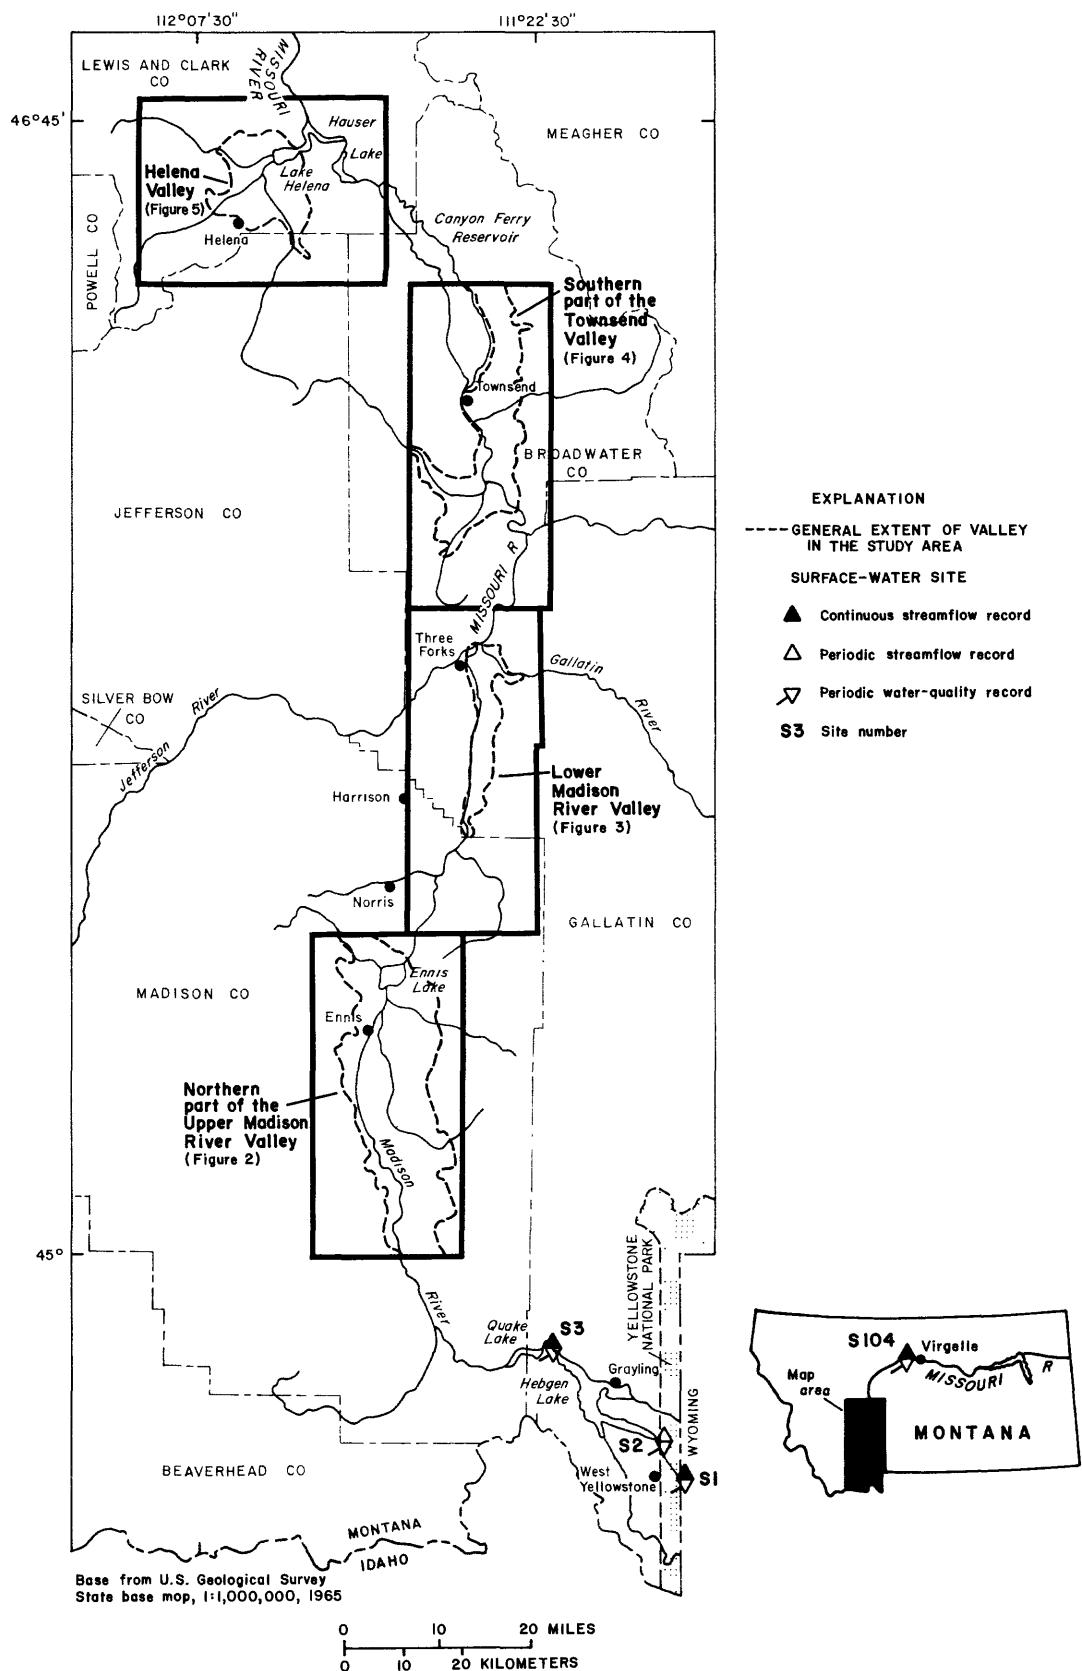

ence samples, interlaboratory comparison samples, and field blanks.

## **INTRODUCTION**

Geothermal waters in Yellowstone National Park contribute large quantities of arsenic to the headwaters of the Madison River (fig. 1). The median total-recoverable arsenic concentration in water from the Madison River near West Yellowstone is 280 µg/L. The Madison River joins the Jefferson and Gallatin Rivers near Three Forks to form the upper Missouri River, where the median total-recoverable arsenic concentration in streamflow is about 74 µg/L. Farther downstream, below Canyon Ferry Lake near Helena, the median total-recoverable arsenic concentration in streamflow is 27 µg/L (Knapton and Horpestad, 1987; Knapton and Brosten, 1987, 1989; U.S. Geological Survey, published annually). Water in some Quaternary and Tertiary valley-fill deposits along the Madison and upper Missouri Rivers also is locally enriched in arsenic. Arsenic concentrations in ground water are highest in the lower Madison River Valley near Three Forks, where an arsenic concentration as high as 176 µg/L has been reported (Sonderegger and Sholes, 1989).

Water from the Missouri River is not used for municipal supply upstream from Canyon Ferry Lake; however, domestic and public-supply wells exist in areas where arsenic concentrations in ground water are high. Recent increases in residential development, particularly near the flood plains and on adjacent terraces, have resulted in additional wells in areas of high arsenic concentrations.

Arsenic in surface and ground water in the Madison and upper Missouri River Valleys is an important public-health concern. Arsenic concentrations in the

**Figure 1.** Location of study area in Montana.

**2 Hydrologic and Water-Quality Data Related to the Occurrence of Arsenic for Areas Along the Madison and Upper Missouri Rivers, Southwestern and West-Central Montana**

Madison and upper Missouri Rivers and some ground water exceed the State of Montana water-quality human health standard of 18 µg/L (Montana Department of Environmental Quality, 1995) as well as the U.S. Environmental Protection Agency Maximum Contaminant Level (MCL) of 50 µg/L (U.S. Environmental Protection Agency, 1996). The extent of affected areas and the mechanisms that control arsenic concentrations in surface and ground water in the Madison and upper Missouri Rivers are relatively unknown.

The Montana Department of Natural Resources and Conservation (MDNRC) adopted standards in 1992 that prevent new irrigation projects if water diverted for irrigation increases arsenic concentrations in surface or ground water. A better understanding of the historic effects of irrigation on arsenic in surface and ground water was needed to be able to predict the effect that proposed new irrigation would have on arsenic concentrations. Consequently, the U.S. Geological Survey (USGS), in cooperation with the MDNRC and the Bureau of Reclamation (BOR), conducted a study to obtain additional information to meet these needs.

This report presents hydrologic and water-quality data for the Madison and upper Missouri Rivers and selected tributaries, irrigation supply canals or ditches, drains, springs and seeps, for Lake Helena, and for ground water in adjacent areas. Hydrologic and water-quality data were collected and compiled during 1992–1995 to provide information to more fully understand the extent, magnitude, and source of arsenic in surface and ground water along the Madison and upper Missouri Rivers; to assess, to the extent possible, the mechanisms that control arsenic concentrations; and to assess the effect of irrigation on arsenic concentrations. The data presented were obtained by the USGS and other agencies during this and previous studies.

## Description of the Study Area

The study area consists of about 2,320 mi<sup>2</sup> located within Madison, Gallatin, Jefferson, Broadwater, and Lewis and Clark Counties in southwestern and west-central Montana. The study area extends from West Yellowstone to the Helena Valley and is divided into four areas where stream water has been diverted for irrigation: the northern part of the upper Madison River Valley, the lower Madison River Valley, the southern part of the Townsend Valley, and the Helena

Valley. Additionally, three surface-water sites (S1, S2, and S3) are located southeast of the upper Madison River Valley near West Yellowstone to Quake Lake and one surface-water site (S104) is located downstream from the Helena Valley at Virgelle (fig. 1).

These valleys are filled with generally permeable, unconsolidated to consolidated Tertiary to Quaternary deposits, which form modern flood plains, terraces, alluvial fans, and benches. This valley fill forms a complexly stratified sequence of gravel, sand, silt, and clay that can be several thousand feet thick. Valleys are surrounded by mountains composed of generally impermeable Archean to Quaternary bedrock or Tertiary semiconsolidated, fine-grained sediments.

The northern part of the upper Madison River Valley (fig. 2) extends from south of Cameron to north of Ennis Lake. About 10,000 acres of land primarily located on the Cameron Bench and along the West Madison Canal are irrigated. Water is diverted for irrigation from the Madison River and some of its major tributaries, which include Indian, O'Dell, Bear, and Blaine Spring Creeks; therefore, many areas are irrigated from a mixture of water from the Madison River and its tributaries. The main supply canals include Granger and Shewmaker Ditches, an unnamed canal that diverts water from O'Dell Creek to the Jeffers area, and the West Madison Canal. Water has been diverted for irrigation to some areas in the upper Madison River Valley for more than 80 years (Keith, 1995). Irrigated crops consist of alfalfa and native grass; some irrigated land is used for pasture.

The lower Madison River Valley (fig. 3) extends from near Elk Creek to near Trident. About 5,900 acres of land located mostly between the river and prominent cliffs of the Madison Plateau to the east are irrigated. Water is diverted for irrigation from the Madison River near Elk Creek to near the Missouri River north of Three Forks, as well as from two creeks (Spring and Rey Creeks) that originate as springs on the valley floor. Some areas are sub-irrigated by shallow ground water. The main supply canals include Sloan, Hutchinson, Crowley, and Darlington Ditches, and Dell, Spring and Rey Creeks on the east side of the valley, and the Francis Walbert Ditch on the northwest side of the valley. Water has been diverted for irrigation to some areas in the lower Madison River Valley for more than 90 years (Keith, 1995). Irrigated crops consist of cereal grains, alfalfa, and native grass; some irrigated land is used for pasture.

The southern part of the Townsend Valley (fig. 4) extends from Plunket Lake to north of Townsend along the east side of Canyon Ferry Lake. About 31,700 acres of land are irrigated. Water is diverted from the Missouri River from near Toston to as far north as Duck Creek and some diversions include a mixture of water from tributaries and ground water. The main supply canals include Toston Canal, Warm Springs Creek, Broadwater-Missouri Westside Canal, Broadwater Missouri Canal and Montana Ditch. Water has been diverted for irrigation to some areas in the Townsend Valley for more than 100 years (Lorenz and McMurtrey, 1956). Irrigated crops consist of cereal grains, seed potatoes, alfalfa, and native grass; some irrigated land is used for pasture.

The Helena Valley (fig. 5) extends from Helena and the Scratchgravel Hills northeast to Lake Helena. About 21,200 acres of land are within the irrigation district. Water is diverted from the Missouri River and is pumped to the Helena Valley Regulating Reservoir. Water is then released to the Helena Valley Canal and its extensive network of distributary canals and ditches. Water is also diverted from Prickly Pear, Tenmile, and Sevenmile Creeks; therefore, some irrigated areas include a mixture of water from these sources. Some areas are sub-irrigated by shallow ground water. Water has been diverted for irrigation to some areas in the Helena Valley for more than 100 years (Lorenz and Swenson, 1951). Irrigated crops consist of cereal grains, alfalfa, and native grass; some irrigated land is used for pasture.

## Site-Numbering Systems

For clarity, surface-water sites are assigned a site number from S1 through S104 in downvalley order (table 1). (All tables are at the back of the report.) Eight-digit station-identification numbers for routine surface-water sites represent the standard USGS numbering system for streamflow-gaging stations. Fifteen-digit station-identification numbers are used for miscellaneous or temporary surface-water stations; these numbers represent the approximate latitude and longitude of this site (first 13 digits), plus the sequence number (last 2 digits).

Ground-water sites are assigned location numbers according to their geographic position within the rectangular grid system used for the subdivision of public lands (fig. 6). The location number consists of

as many as 14 characters. The first three characters specify the township and its position north or south (N or S) of the Montana Base Line. The next three characters specify the range and its position east or west (E or W) of the Montana Principal Meridian. The next two characters are the section number. The next two to four alpha characters designate the quarter section (160-acre tract), the quarter-quarter section (40-acre tract), the quarter-quarter-quarter section (10-acre tract), and the quarter-quarter-quarter-quarter section (2.5-acre tract), respectively, in which the well is located. These four subdivisions of the section are designated A,B,C, and D in a counter-clockwise direction, beginning in the northeast quadrant. The last two numeric characters specify a sequence number, based on the order of inventory, to distinguish between multiple wells at a single location. For example, as shown in figure 6, well 11N03W33BBAA02 is the second well inventoried in the NE 1/4 NE 1/4 NW1/4 NW1/4 sec. 33, T. 11 N., R. 3 W.

## Acknowledgments

The authors acknowledge with appreciation the many individuals who assisted in the study. Particular thanks are given to the many landowners in the study area for allowing access to their property. Appreciation is also extended to Andrew R. Skerda, Steven W. Nichols, Kevin L. Sattler, Ranald G. Cramer, and David W. Clark (USGS) for assisting in the collection of hydrologic and water-quality data; and to Charles E. Dalby (MDNRC), Jeff Lucero (BOR), Joanna N. Thamke, and Kent A. Dodge (USGS) for colleague review.

## SAMPLING LOCATIONS AND TYPES OF DATA

Surface water was sampled at 40 sites on the Madison and upper Missouri Rivers and selected tributaries from West Yellowstone to Virgelle (fig. 1-5, tables 1-9). Sites were selected on the basis of available historical hydrologic and water-quality data. Selected tributaries were sampled to describe hydrologic and water-quality characteristics of water entering the Madison and upper Missouri Rivers and to document other possible sources of arsenic. In addition, water-quality data were obtained for six diel (or daily) investigations at five mainstem sites located on the Madison and upper Missouri Rivers (tables 4-9).

ment Canyon Ferry Dam, 1975, 1:100,000

**Figure 6.** Numbering system for ground-water sites along the Madison and upper Missouri Rivers in Montana.

Surface water was also sampled at 64 sites on irrigation canals, ditches, drains, springs and seeps, and Lake Helena. Most of these sites were selected either on the basis of data available from the BOR (Mangelson and Brummer, 1994) or to provide data for areas not covered by existing data sources.

Ground-water sites were selected along the Madison and upper Missouri Rivers from south of Cameron to the northern part of the Helena Valley (fig. 1-5, tables 10-12). Sites were chosen based on review of hydrologic and arsenic-concentration data available from previous studies, drillers' logs, and to provide data in areas not covered by existing data sources. Hydrologic or arsenic-concentration data were obtained for 273 ground-water sites.

Most ground-water sites in the upper and lower Madison River Valleys were selected because arsenic-concentration data were available from previous studies. Data for some sites in the upper Madison River Valley had been collected by the USGS and were retrieved from WATSTORE. Data for most sites in the lower Madison River Valley were retrieved from the Montana Bureau of Mines and Geology (MBMG). Most of these sites are reported in Sonderegger and Sholes (1989) or Sonderegger and others (1989).

Ground-water sites from the MBMG were not field checked by the USGS. Additionally, drillers' logs were obtained for these sites and hydrologic data from the drillers' logs were used as part of this study to help in understanding the hydrogeology of the lower Madison River Valley.

Privately owned water wells were inventoried during 1992-1995 to obtain ground-water data in areas not covered by existing data sources. Hydrologic and field water-quality data were collected as part of the inventory (table 10). Drillers' logs were obtained for most of these sites and compiled as part of this study. Water samples were collected from many of these wells in 1992-95 (tables 11 and 12).

## METHODS OF SAMPLE COLLECTION, PROCESSING, AND ANALYSIS

Surface-water samples were collected using either cross-sectional, depth-integrated methods described by Edwards and Glysson (1988), U.S. Geological Survey (1977), and Knapton (1985) for larger streamflows or grab methods described by Knapton (1985) for smaller streamflows (tables 2-9). Sampling equipment consisted of standard USGS depth-integrat-

ing suspended-sediment samplers, which were either constructed of plastic or coated with non-metallic epoxy paint and equipped with nylon nozzles. Instantaneous discharge was determined by direct measurement, from stage-discharge ratings, or estimation (Rantz and others, 1982). Water temperature, specific conductance, pH, and dissolved oxygen were determined during collection of water-quality samples. Field processing of surface-water samples was performed according to procedures described by Ward and Harr (1990), U.S. Geological Survey (1977), and Knapton (1985).

Suspended-sediment samples also were collected when some water-quality samples were collected at selected surface-water sites. These samples were analyzed by the USGS Montana District office for suspended-sediment concentration and sand-silt distribution (percent finer than 0.062-mm diameter) according to methods described by Guy (1969) and Lambing and Dodge (1993).

Samples for six diel investigations were collected at about 1-hour intervals for 1- to 2-day periods at five mainstem sites (tables 4-9). Depth-integrated samples were collected at a single vertical at sites within the active flow of the channel, where the water was well-mixed, and as far from the river's edge as could be safely waded at night.

Ground-water samples (tables 11 and 12) were collected using a variety of samplers and were processed as described by Knapton (1985). Samples from domestic and stock wells were obtained using the existing pump and at a discharge point as close to the well as possible. Most wells had submersible pumps; however, a few wells had jet pumps, which can cause aeration and, possibly, chemical changes in the water. Test wells installed by Sonderegger and others (1989) and Briar and Madison (1992) were sampled with a stainless steel submersible pump. All wells were purged until at least three well volumes of water were removed and field parameters measured onsite (water temperature, specific conductance, pH, and dissolved oxygen) had stabilized. Field parameters were measured in a flow-through chamber for all wells. Field values for alkalinity were determined by incremental titration of the sample with sulfuric acid. Samples for arsenic speciation were filtered and preserved with hydrochloric acid. Water samples analyzed for oxygen-18/oxygen-16 (O-18/O-16) and deuterium/hydrogen (D/H) isotopic ratios were not filtered or preserved.

Water chemistry samples were analyzed by one of three laboratories: USGS National Water Quality Laboratory, Arvada, Colo.; MBMG Analytical Division, Butte, Mont.; or BOR, Bismarck, N.D. Samples submitted to the USGS were analyzed using methods described by Fishman and Friedman (1989) and Fishman (1993).

Dissolved arsenic was determined on samples filtered through 0.45- $\mu\text{m}$  pore-size filter. Total-recoverable arsenic was determined on unfiltered samples. Samples sent to the USGS were analyzed by hydride generation atomic absorption spectrometry after a sulfuric acid-potassium persulfate digestion designed to liberate organic arsenic-containing compounds as described by Fishman and Friedman (1989). Samples sent to the MBMG laboratory were analyzed by inductively-coupled plasma-mass spectrometry with no digestion before analysis as described by American Public Health Association and others (1992). Samples sent to the BOR laboratory were analyzed by graphite furnace atomic absorption after a nitric acid digestion as described by American Public Health Association and others (1992). Minimum reporting levels and policies regarding significant figures varied among the three laboratories. Arsenic data are reported as received from each laboratory.

Analyses for arsenic species were performed for selected ground-water samples by the MBMG using hydride generation atomic absorption spectrometry. For this analysis, the concentration of arsenite plus arsenate ( $\text{As}^{+3}$  and  $\text{As}^{+5}$ , shown in tables 12, 15, and 17) was determined on subsamples that were reduced in the laboratory with concentrated hydrochloric acid. The concentration of arsenite ( $\text{As}^{+3}$ , shown in tables 12, 15, and 17) was determined from subsamples that were not reduced with concentrated hydrochloric acid in the laboratory. The concentration of arsenate then can be calculated as the difference between the concentration of arsenite plus arsenate and the concentration of arsenite.

## QUALITY ASSURANCE AND QUALITY CONTROL

Quality-assurance procedures used for collecting and field processing of water-quality samples are described by Ward and Harr (1990), Edwards and Glysson (1988), Knapton and Nimick (1991), and Knapton (1985). For water samples submitted to the

USGS, standard procedures for internal sample handling and quality assurance are described by Friedman and Erdman (1982), Jones (1987), and Pritt and Raese (1992). For suspended-sediment samples submitted to the USGS Montana District, standard procedures for sample handling and quality assurance are described by Lambing and Dodge (1993).

The quality of arsenic concentrations determined for this study was evaluated by quality-control samples that were submitted from the field and analyzed in the laboratory with routine surface- and ground-water samples. Quality-control samples consisted of replicates, standard reference samples (SRS), interlaboratory comparison samples, and field blanks (tables 13-17). These quality-control samples provided information on the precision or bias of laboratory analyses, presence and magnitude of possible equipment or sample contamination, or comparability of arsenic data from different laboratories.

Replicate samples are two or more samples considered to be identical. Analyses of replicate samples indicate the precision, or reproducibility, of environmental data, which is affected by the combined variability of field and laboratory processes to which the sample is exposed. The precision, or reproducibility, of arsenic data was evaluated by computing the relative standard deviation (RSD) of arsenic concentrations measured in one set of replicate, standard reference, or interlaboratory samples. The RSD provides estimates of the variation that can be expected for arsenic concentrations reported for this study. No RSD's were calculated when one or both of the replicate concentrations was less than the minimum reporting level. RSD's were computed from the equation:

$$RSD = \frac{\text{standard deviation of values}}{\text{mean of values}} \times 100 \quad (1)$$

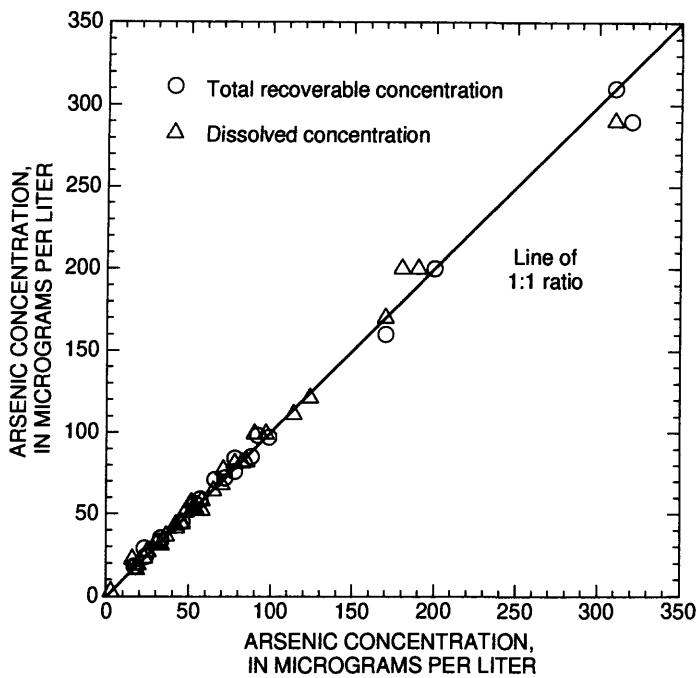

Replicate samples were submitted individually to the USGS and the MBMG. The USGS alone analyzed 22 replicate samples for total-recoverable arsenic and 24 replicate samples for dissolved arsenic. The RSD's for these samples were less than 9 percent except for one value of about 16 percent. MBMG alone analyzed

15 replicate samples for dissolved arsenic. The RSD's for these samples were less than 7 percent except for one value of about 25 percent (fig. 7, tables 13-15).

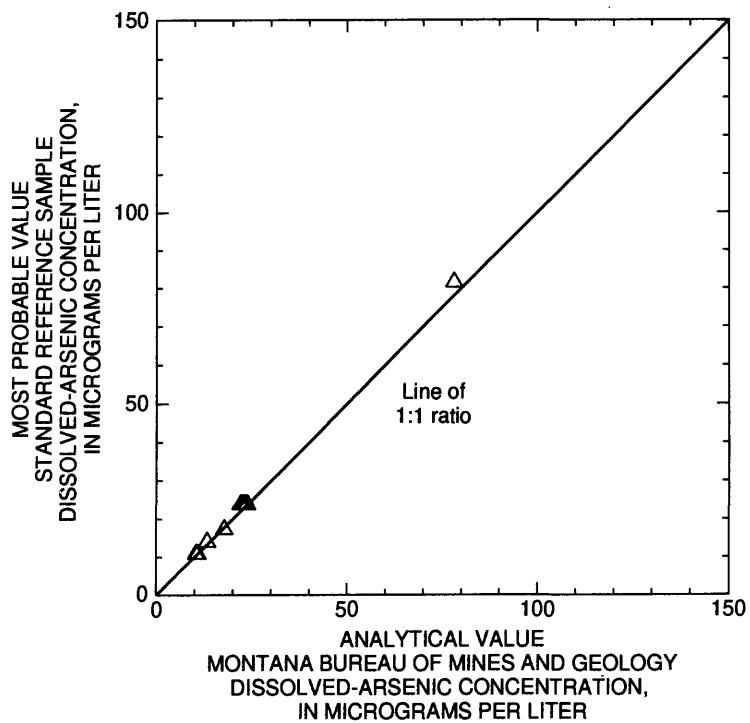

Data from SRS's indicate the accuracy or ability to measure a known concentration. These samples are not processed in the field, but are sent directly to the laboratory for analysis, and thus provide quality-assurance data primarily on laboratory procedures. Concentrations for SRS's are assumed to be the median, or most probable value, for any given constituent from many analyses performed as part of the USGS's interlaboratory evaluation program (H.K. Long and J.W. Farrar, U.S. Geological Survey, written commun., 1989, 1991; Long and Farrar, 1992). MBMG analyzed 10 SRS's for common-ion and trace-element data including arsenic (table 16). Only RSD's for arsenic were calculated and all values were less than 6 percent (fig. 8).

Replicates were also divided between different laboratories to evaluate interlaboratory precision. Nine replicates were sent to the USGS and MBMG, 27 replicates were sent to the MBMG and BOR, and 4 replicates were sent to the USGS and BOR. The RSD's for dissolved-arsenic concentration for the 9 sets of replicates sent to the USGS and MBMG ranged from about 0.6 percent to about 27 percent (fig. 9, tables 14 and 15). The RSD's for dissolved-arsenic concentration for the 27 sets of replicates sent to the BOR and MBMG ranged from about 0.1 percent to about 31 percent (fig. 10, table 14). Twenty-one of 27 RSD's were less than about 10 percent; for the four replicate sets with RSD's of more than about 10 percent, arsenic concentrations were near the minimum reporting level and ranged from 0.7 to 5.1. The RSD's for dissolved-arsenic concentration for the four sets of replicates sent to the BOR and USGS ranged from about 2.5 percent to about 15 percent, with three of the four values being more than 10 percent (fig. 11, table 14).

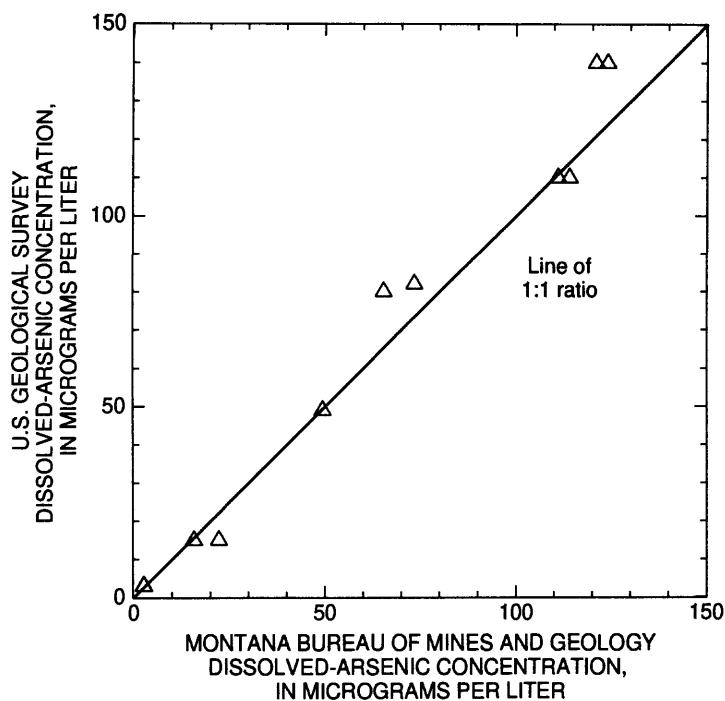

Analytical results for field blanks are presented in table 17. Blanks are aliquots of deionized water that are processed through sampling equipment used to collect environmental samples and subjected to the same subsequent processing as environmental samples. A field blank with constituent concentrations equal to or less than the minimum reporting level for the analytical

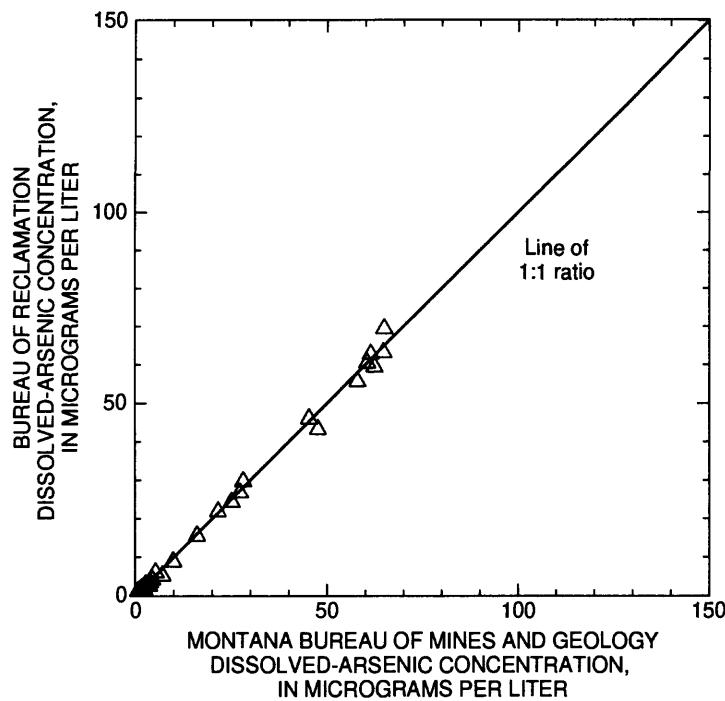

**Figure 7.** Relation between arsenic-concentration data for replicate samples analyzed either by the U.S. Geological Survey or the Montana Bureau of Mines and Geology laboratories.

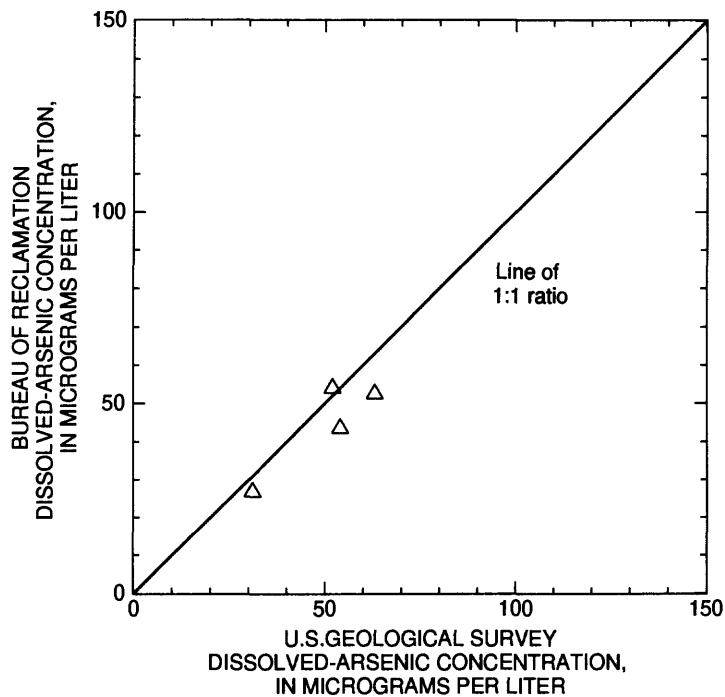

**Figure 8.** Relation between dissolved-arsenic concentration data from the Montana Bureau of Mines and Geology laboratory and the most probable value for standard reference samples.

**Figure 9.** Relation between dissolved-arsenic concentration data from the Montana Bureau of Mines and Geology and the U.S. Geological Survey laboratories.

**Figure 10.** Relation between dissolved-arsenic concentration data from the Montana Bureau of Mines and Geology and the Bureau of Reclamation laboratories.

**Figure 11.** Relation between dissolved-arsenic concentration data from the U.S. Geological Survey and the Bureau of Reclamation laboratories.

method indicates that the entire sample-collection, processing, and analytical process is presumably free of significant contamination for those constituents. Exceedances of twice the minimum reporting level probably represent contamination or instrument calibration error. Six field blanks were submitted to either the USGS or MBMG. All values for arsenic in field blanks were below the minimum reporting level. Exceedances of twice the minimum reporting level include calcium (on 08-13-92), chloride (on 08-13-92), fluoride (09-21-92 and 09-23-92), silica (all 1992 samples), barium (on 09-21-92 and 09-23-92), and iron (on 09-21-92 and 09-23-92). No adjustments were made to analytical results.

**Table 3.** Water-quality data used as geothermal tracers for selected surface-water sites along the Madison and upper Missouri Rivers in Montana

[Constituents are reported as dissolved. Significant figures for arsenic concentrations are those reported by the respective laboratories; other concentrations are rounded according to standard USGS procedures. Site number described in text. Collecting or analyzing agency: BOR, Bureau of Reclamation Laboratory, Bismarck, N.D.; MBMG, Montana Bureau of Mines and Geology, Analytical Division, Butte, Mont.; USGS, U.S. Geological Survey, National Water Quality Laboratory, Arvada, Colo. Abbreviations: ft<sup>3</sup>/s, cubic feet per second; °C, degrees Celsius; e, estimated; µg/L, micrograms per liter; µS/cm, microsiemens per centimeter at 25 °C; mg/L, milligrams per liter. Symbols: <, less than minimum reporting level; --, no data]

Site number	Sample date	Discharge, instantaneous <sup>1</sup> (ft <sup>3</sup> /s)	Specific conductance <sup>2</sup> (µS/cm)	pH <sup>2</sup> (standard units)	Temperature, water (°C)	Chloride (mg/L as Cl)	Arsenic <sup>3</sup> (µg/L as As)	Boron, (µg/L as B)	Lithium (µg/L as Li)	Collecting agency	Analyzing agency

<sup>1</sup>Discharge values reported as ranges by the Bureau of Reclamation were averaged.

<sup>2</sup>Values determined by the Bureau of Reclamation are laboratory values; values determined by the U.S. Geological Survey are field values.

<sup>3</sup>Samples collected for the Bureau of Reclamation by U.S. Geological Survey personnel were unfiltered samples.

**Table 4.** Water-quality data for diel investigations of the Madison River near West Yellowstone, Montana, August 24-26, 1990

[Site number is S1 in table 1. Constituents are reported as dissolved. Laboratory analyses and field measurements by U.S. Geological Survey. Abbreviations: °C, degrees Celsius; µg/L, micrograms per liter; µS/cm, microsiemens per centimeter at 25 °C; mg/L, milligrams per liter. Symbol: --, no data]

**Table 10.** Records of wells along the Madison and upper Missouri Rivers in Montana

Location number--described in text.

Geologic unit--Qal, alluvial deposits (Quaternary); Ts, sedimentary deposits (Tertiary); QAb bedrock (Quaternary to Archean).

Altitude of land surface--in feet above sea level.

Primary use of water--C, commercial; H, domestic; I, irrigation; N, industrial; P, public supply; S, stock; U, unused.

Depth of well--in feet below land surface.

Type of finish--F, gravel perforated; G, screen with gravel; O, open end; P, perforated or slotted; S, screen; T, sand point; X, open hole.

Top of open interval--in feet below land surface.

Water level--in feet below or above (+) land surface.

Source of water-level data--A, other government agency; D, driller; O, owner; R, Montana Bureau of Mines and Geology or Montana Department of Environmental Quality; S, U.S. Geological Survey.

Source of discharge data--A, other government agency; D, driller; O, owner; R, Montana Bureau of Mines and Geology or Montana Department of Environmental Quality; S, U.S. Geological Survey.

Source of water-quality data--MBMG, Montana Bureau of Mines and Geology; USGS, U.S. Geological Survey.

Abbreviations--°C, degrees Celsius; gal/min, gallons per minute; µS/cm, microsiemens per centimeter at 25 °C; mg/L, milligrams per liter.

Symbols: -, or --, no data.

**Table 11.** Physical properties and common-constituent concentrations in ground water along the Madison and upper Missouri Rivers in Montana

[Constituents are reported as dissolved, except as indicated and values are rounded according to standard USGS procedures. Analyses by Montana Bureau of Mines and Geology Analytical Division, Butte, Mont. Analyses in the upper Madison River Valley for 08-17-92 through 08-19-92 and in the lower Madison River Valley for 08-15-91 were analyzed by the U.S. Geological Survey, National Water Quality Laboratory, Arvada, Colo. Location number: described in text. Geologic unit: Qal, alluvial deposits (Quaternary); Ts, sedimentary deposits (Tertiary); QAb, bedrock (Quaternary to Archean). Collecting agency: MBMG, Montana Bureau of Mines and Geology; USGS, U.S. Geological Survey. Abbreviations: °C, degrees Celsius; µS/cm, microsiemens per centimeter at 25 °C; mg/L, milligrams per liter. Symbols: <, less than minimum reporting level; --, no data]

Location number	Geo-logic unit	Sample date	Spe-cific con-duc-tance, field (µS/cm)	pH, field (stand-ard units)	Temper-ature, water (°C)	Oxygen, dis-solved, field (mg/L)	Calcium (mg/L as Ca)	Magne-sium (mg/L as Mg)	Sodium (mg/L as Na)	Potas-sium (mg/L as K)

**Table 12.** Trace-element concentrations and isotope ratios in ground water along the Madison and upper Missouri Rivers in Montana

[Constituents are reported as dissolved and values are rounded according to standard USGS procedures except for arsenic. Analyses by the Montana Bureau of Mines and Geology, Analytical Division, Butte, Mont. Analyses of nine samples from the upper Madison River Valley for 08-17-92 through 08-19-92 and two samples from the lower Madison River Valley for 08-15-91 were analyzed by the U.S. Geological Survey, National Water Quality Laboratory, Arvada, Colo. Location number: described in text. Geologic unit: Qal, alluvial deposits (Quaternary); Ts, sedimentary deposits (Tertiary); QAb, bedrock (Quaternary to Archean). Collecting agency: MBMG, Montana Bureau of Mines and Geology, Butte, Mont.; USGS, U.S. Geological Survey. Abbreviations:  $\mu\text{g/L}$ , micrograms per liter; per mil, parts per thousand; TU, tritium units. Symbols: +3 and +5, oxidation states of arsenic--arsenite and arsenate, respectively; <, less than minimum reporting level; --, no data]

Location number	Geo-logic unit	Sample date	Alumi-num ( $\mu\text{g/L}$ as Al)	Arse-nic, As <sup>+3</sup> and As <sup>+5</sup> ( $\mu\text{g/L}$ as As)	Arse-nic <sup>+3</sup> ( $\mu\text{g/L}$ as As)	Bar-lum ( $\mu\text{g/L}$ Ba)	Beryl-lum ( $\mu\text{g/L}$ as Be)	Bo-ron ( $\mu\text{g/L}$ as B)	Cad-mium ( $\mu\text{g/L}$ as Cd)	Chro-mium ( $\mu\text{g/L}$ as Cr)	Cop-per ( $\mu\text{g/L}$ as Cu)	Iron ( $\mu\text{g/L}$ as Fe)

**Table 13.** Water-quality data for replicate surface-water samples

[Constituents are reported as dissolved except as indicated. Number of significant figures for arsenic concentrations are those reported by the respective laboratories; other concentrations are rounded according to standard USGS procedures. Site number described in text. Analyzing agency: USGS, U.S. Geological Survey, National Water Quality Laboratory, Arvada, Colo.; MBMG, Montana Bureau of Mines and Geology, Analytical Division, Butte, Mont. Abbreviations: lab, laboratory;  $\mu\text{g/L}$ , micrograms per liter;  $\mu\text{S/cm}$ , microsiemens per centimeter at  $25^\circ\text{C}$ ;  $\text{mg/L}$ , milligrams per liter. Symbols: <, less than minimum reporting level; --, no data]

Site number	Sample date	Specific conductance, lab ( $\mu\text{S/cm}$ )	pH, lab (standard units)	Calcium ( $\text{mg/L}$ as Ca)	Magnesium ( $\text{mg/L}$ as Mg)	Sodium ( $\text{mg/L}$ as Na)	Potassium ( $\text{mg/L}$ as K)	Alkalinity, lab ( $\text{mg/L}$ as $\text{CaCO}_3$ )	Sulfate ( $\text{mg/L}$ as $\text{SO}_4$ )	Chloride ( $\text{mg/L}$ as Cl)	Fluoride ( $\text{mg/L}$ as F)

**Table 15.** Water-quality data for replicate ground-water samples

[Constituents are reported as dissolved. Number of significant figures for arsenic concentrations are those reported by the respective laboratories; other concentrations are rounded according to standard USGS procedures. Location number described in text. Analyzing agency: MBMG, Montana Bureau of Mines and Geology, Analytical Division, Butte, Mont.; USGS, U.S. Geological Survey National Water Quality Laboratory, Arvada, Colo. Abbreviations: lab, laboratory; µg/L, micrograms per liter; µS/cm, microsiemens per centimeter at 25° Celsius; mg/L, milligrams per liter. Symbols: +3 and +5, oxidation states of arsenic--arsenite and arsenate, respectively; <, less than minimum reporting level; --, no data]

Location number	Sample date	Specific conductance, lab (µS/cm)	pH, lab (standard units)	Calcium (mg/L as Ca)	Magnesium (mg/L as Mg)	Sodium (mg/L as Na)	Potassium (mg/L as K)	Alkalinity, lab (mg/L as CaCO <sub>3</sub> )	Sulfate (mg/L as SO <sub>4</sub> )	Chloride (mg/L as Cl)

**Table 18.** Water Data Storage and Retrieval System (WATSTORE) codes and parameter names for selected physical and water-quality parameters used in this report

[Abbreviations: ft<sup>3</sup>/s, cubic feet per second; °C, degrees Celsius; µg/L, micrograms per liter; µS/cm, microsiemens per centimeter at 25° C; mg/L, milligrams per liter; mm, millimeter; permil, parts per thousand; TU, tritium unit]

WATSTORE <sup>1</sup> code	WATSTORE parameter name
00020	Air temperature (°C)
90410	Alkalinity ((mg/L as CaCO <sub>3</sub> )
00419, 39086 <sup>2</sup>	Alkalinity, field (mg/L as CaCO <sub>3</sub> )
01106	Aluminum - dissolved (µg/L as Al)
30010	Analyzing agency, Montana Bureau of Mines and Geology
80020	Analyzing agency, U.S. Geological Survey
01095	Antimony - dissolved (µg/L as Sb)
01000	Arsenic - dissolved (µg/L as As)
01002	Arsenic - total recoverable (µg/L as As)
01005	Barium - dissolved (µg/L as Ba)
01010	Beryllium - dissolved (µg/L as Be)
00450, 00453 <sup>2</sup>	Bicarbonate, field (mg/L as HCO <sub>3</sub> ) <sup>3</sup>
01020	Boron - dissolved (µg/L as B)
01025	Cadmium - dissolved (µg/L as Cd)
00915	Calcium - dissolved (µg/L as Ca)
00447, 00452	Carbonate, field (mg/L as CO <sub>3</sub> ) <sup>3</sup>
00940	Chloride - dissolved (mg/L as Cl)
01030	Chromium - dissolved (µg/L as Cr)
01040	Copper - dissolved (µg/L as Cu)
DATES	Date of sample
82082	Deuterium/hydrogen stable-isotope ratio (permil)
00061	Discharge - instantaneous (ft <sup>3</sup> /s)
70301	Dissolved solids - calculated (mg/L)
00950	Fluoride - dissolved (mg/L as F)
GUNIT	Geologic unit
01046	Iron - dissolved (µg/L as Fe)
01049	Lead - dissolved (µg/L as Pb)
01130	Lithium - dissolved (µg/L as Li)
00925	Magnesium - dissolved (µg/L as Mg)
01056	Manganese - dissolved (µg/L as Mn)
01060	Molybdenum - dissolved (µg/L as Mo)
01065	Nickel - dissolved (µg/L as Ni)
00618	Nitrate - dissolved (mg/L as N)
99900 <sup>3</sup>	Nitrate, field - dissolved (mg/L as N)
00300	Oxygen, field - dissolved (mg/L)
00301	Oxygen, field (percent saturation)
82085	Oxygen-18/oxygen-16 stable isotope ratio (permil)
00671	Phosphorus, orthophosphate - dissolved (mg/L as P)
00400	pH - field (standard units)
00935	Potassium - dissolved (mg/L as K)
80154	Sediment - suspended (mg/L)
80155	Sediment - percent finer than 0.062 mm
01145	Selenium - dissolved (µg/L as Se)
00955	Silica - dissolved (mg/L as SiO <sub>2</sub> )
00930	Sodium - dissolved (mg/L as Na)
00095	Specific conductance, field (µS/cm)
01080	Strontium - dissolved (µg/L as Sr)
00945	Sulfate - dissolved (mg/L as SO <sub>4</sub> )
07000	Tritium, whole water (TU)
00010	Water temperature, field (°C)
01090	Zinc - dissolved (µg/L as Zn)

<sup>1</sup>Analytical methods for the U.S. Geological Survey, National Water Quality Laboratory are fully described in Fishman and Friedman, 1989, and Fishman, 1993.

<sup>2</sup>The first WATSTORE code refers to incremental titration with an unfiltered sample, whereas the second WATSTORE code refers to incremental titration with a filtered sample.

<sup>3</sup>U.S. Geological Survey, Montana District use only. Nitrate value determined in the field with a spectrophotometer.
